Lecture 1, part 1

Introduction
Combustion

• Mass and energy conversion process

• Chemical bond energy $\rightarrow$ thermal energy

• Fuel reacts with the oxygen of the air $\rightarrow$ products (mainly carbon dioxide and water) with lower enthalpy of formation or reference enthalpy than the reactants
Aim of this course

• Develop understanding of combustion processes from physical and chemical perspectives

• Fundamentals:
  – Thermodynamics
  – Fluid mechanics
  – Heat and mass transfer

• Applications:
  – Reciprocating engines
  – Gas turbines
  – Furnaces
Topics

- Combustion thermodynamics and chemical equilibrium

- **Interaction** von flow (transport) and chemistry
  - Laminar and turbulent combustion
  - New dimensionless groups (similar to Reynolds number)

- Mathematical analysis tools
  - Asymptotic analysis
Combustion Applications: Examples

- Jet flame
  - Cigarette lighter

- Spark-ignition engine
  - Premixed

- Aircraft engine
  - Non-premixed
Jet Diffusion Flame

- Fuel emanating from separate nozzle mixes with surrounding air
- Mixing by molecular and turbulent diffusion (transport)
- Diffusion typically slower than chemical reactions
- Diffusion rate determining
Diffusion Flame Structure

Lecture 1, part 2

Thermodynamics and Mass Balances of Combustion Systems
The final state of a homogeneous system is governed by the classical balance laws of thermodynamics.

Prerequisites:

- Definitions of concentrations and thermodynamic variables
- Mass and energy balances for multicomponent systems
Mole Fractions and Mass Fractions

• In chemical reactions mass and chemical elements are conserved

The Mole Fraction

• Multi-component system with $k$ different chemical species

• Mole: $6.0236 \times 10^{23}$ molecules are defined as one mole

• Number of moles of species $i$: $n_i$

• Total number of moles: $n_s = \sum_{i=1}^{k} n_i$

• Mole fraction of species $i$: $X_i \equiv \frac{n_i}{n_s}, \quad i = 1, 2, \ldots, k$
The Mass Fraction

- Mass $m_i$ of all molecules of species $i$ is related to its number of moles by

$$m_i = W_i n_i, \quad i = 1, 2, \ldots, k$$

where $W_i$ is the molecular weight of species $i$

- Total mass of all molecules in the mixture:

$$m = \sum_{i=1}^{k} m_i$$

- Mass fraction of species $i$:

$$Y_i = \frac{m_i}{m}, \quad i = 1, 2, \ldots, k$$

- Mean molecular weight $W$

$$W = \sum_{i=1}^{k} W_i X_i = \left[ \sum_{i=1}^{k} \frac{Y_i}{W_i} \right]^{-1}$$

- Mass fraction and mole fraction

$$Y_i = \frac{W_i}{W} X_i$$
The mass fraction of elements

• Mass fractions of elements are very useful in combustion

• Mass of the species changes due to chemical reactions, but mass of the elements is conserved

• Mass and molecular weight of all atoms of element $j$ contained in all molecules: $m_j, W_j$

• Number of atoms of element $j$ in a molecule of species $i$: $a_{ij}$

• Mass of all atoms $j$ in the system:

$$m_j = \sum_{i=1}^{k} \frac{a_{ij}W_j}{W_i} m_i, \quad j = 1, 2, \ldots, k_e$$

where $k_e$ is the total number of elements in the system
• The mass fraction of element $j$ is then

$$ Z_j = \frac{m_j}{m} = \sum_{i=1}^{k} \frac{a_{ij}W_j}{W_i} Y_i = \frac{W_j}{W} \sum_{i=1}^{k} a_{ij}X_i, \quad j = 1, 2, \ldots, k_e, $$

• From the definitions above it follows

$$ \sum_{i=1}^{k} X_i = 1, \quad \sum_{i=1}^{k} Y_i = 1, \quad \sum_{j=1}^{k_e} Z_j = 1 $$
The partial molar density (concentration)

• Number of moles per volume $V$ or partial molar density, the concentration:

$$[X_i] = \frac{n_i}{V}, \quad i = 1, 2, \ldots, k$$

• The molar density of the system is then

$$\frac{n_s}{V} = \sum_{i=1}^{k} [X_i]$$
The Partial Density

- The density and the partial density are defined

\[ \rho = \frac{m}{V}, \quad \rho_i = \frac{m_i}{V} = \rho Y_i, \quad i = 1, 2, \ldots, k \]

- The partial molar density is related to the partial density and the mass fraction by

\[ [X_i] = \frac{\rho_i}{W_i} = \frac{\rho Y_i}{W_i}, \quad i = 1, 2, \ldots, k \]
The thermal equation of state

• In most combustion systems of technical interest the law of ideal gases is valid

• Even for high pressure combustion this is a sufficiently accurate approximation because the temperatures are typically also very high

• In a mixture of ideal gases the molecules of species $i$ exert on the surrounding walls of the vessel the partial pressure

\[ p_i = \frac{n_iRT}{V} = [X_i]RT = \frac{\rho Y_iRT}{W_i}, \quad i = 1, 2, \ldots, k \]

• Universal gas constant equal to

\[ \mathcal{R} = 8.3143 \text{ J/mol/K} = 82.05 \text{ atm cm}^3/\text{mol/K} \]
Dalton's law

- For an ideal gas the total pressure is equal to the sum of the partial pressures
- Thermal equation of state for a mixture of ideal gases

\[ p = \sum_{i=1}^{k} p_i = n_s \frac{RT}{V} = \frac{\rho RT}{W} \]

- The partial pressure is equal to the total pressure times the mole fraction

\[ p_i = pX_i, \quad i = 1, 2, \ldots, k \]

- Defining the partial volume by

\[ V_i = \frac{n_i RT}{p}, \quad i = 1, 2, \ldots, k \]

it follows that an equivalent relation exists for the partial volume

\[ V_i = V X_i, \quad i = 1, 2, \ldots, k \]
Stoichiometry

• Equations describing chemical reactions

• Global reactions like $\text{H}_2 + \frac{1}{2}\text{O}_2 = \text{H}_2\text{O}$

or elementary reactions like $\text{H} + \text{O}_2 \overset{k_f}{\underset{k_b}{\rightleftharpoons}} \text{OH} + \text{O}$

are based on the principle of element conservation during reaction

• The stoichiometric coefficients of the reactant $i$: $\nu_i^\prime$

• The stoichiometric coefficients of the product $i$: $\nu_i''$
• If $M_i$ stands for the chemical symbol of species $l$, a reaction equation may be cast into the form

$$\sum_{i=1}^{k} \nu_i' M_i = \sum_{i=1}^{k} \nu_i'' M_i$$

• Net stoichiometric coefficient

$$\nu_i = \nu_i'' - \nu_i', \quad i = 1, 2, \ldots, k$$

is positive for products and negative for reactants

• A system of $r$ elementary reactions may be written

$$\sum_{i=1}^{k} \nu_{il} M_i = 0, \quad l = 1, 2, \ldots, r$$

where the net stoichiometric coefficient of species $i$ in reaction $l$ is: $\nu_{il}$
Coupling Functions

• The stoichiometry defined by the reaction equation relates the molar production or consumption of species to each other

• The change of the number of moles of species $i$ to that of species 1 is

$$\frac{dn_i}{\nu_i} = \frac{dn_1}{\nu_1}, \quad i = 2, \ldots, k$$

• The relation between the partial masses is

$$\frac{dm_i}{\nu_i W_i} = \frac{dm_1}{\nu_1 W_1}, \quad i = 2, \ldots, k$$

• Since the total mass in the system is independent of the chemical reaction (while the total number of moles is not), the relation between mass fractions is

$$\frac{dY_i}{\nu_i W_i} = \frac{dY_1}{\nu_1 W_1}, \quad i = 2, \ldots, k$$
Stoichiometry

• A fuel-air mixture is called stoichiometric, if the fuel-to-oxygen ratio is such that both are entirely consumed when combustion to \( \text{CO}_2 \) and \( \text{H}_2\text{O} \) is completed.

• For example, the global reaction describing the combustion of a single component hydrocarbon fuel \( \text{C}_m\text{H}_n \) (subscript F for fuel)

\[
\nu'_F \text{C}_m\text{H}_n + \nu'_\text{O}_2 \text{O}_2 = \nu''\text{CO}_2 \text{CO}_2 + \nu''\text{H}_2\text{O} \text{H}_2\text{O}
\]

the stoichiometric coefficients are

\[
\nu'_F = 1, \quad \nu'_\text{O}_2 = m + \frac{n}{4}, \quad \nu''\text{CO}_2 = m \quad \nu''\text{H}_2\text{O} = \frac{n}{2}
\]

where \( \nu'_F = 1 \) may be chosen arbitrarily to unity.
• Stoichiometric mixture requires that the ratio of the number of moles of fuel and oxidizer in the unburnt mixture is equal to the ratio of the stoichiometric coefficients

\[ \frac{n_{O_2,u}}{n_{F,u}} \bigg|_{st} = \frac{\nu'_{O_2}}{\nu'_{F}} \]

or in terms of mass fractions

\[ \frac{Y_{O_2,u}}{Y_{F,u}} \bigg|_{st} = \frac{\nu'_{O_2} W_{O_2}}{\nu'_{F} W_{F}} = \nu \]

where \( n \) is called the stoichiometric mass ratio

• Then fuel and oxidizer are both consumed when combustion is completed
• Integrating

\[
\frac{dY_i}{\nu_i W_i} = \frac{dY_1}{\nu_1 W_1}, \quad i = 2, \ldots, k
\]

with \( i = O_2, \ 1 = F \) between the initial unburnt state (subscript \( u \)) and any later state leads to

\[
\frac{Y_{O_2} - Y_{O_2,u}}{\nu'_{O_2} W_{O_2}} = \frac{Y_F - Y_{F,u}}{\nu'_{F} W_{F}}
\]

• This may be written as

\[
\nu Y_F - Y_{O_2} = \nu Y_{F,u} - Y_{O_2,u}
\]
• For a stoichiometric mixture fuel and oxygen are completely consumed at the end of combustion:

\[ Y_F = Y_{O_2} = 0 \]

• Introducing this into

\[ \nu Y_F - Y_{O_2} = \nu Y_{F,u} - Y_{O_2,u} \]

we recover

\[ \frac{Y_{O_2,u}}{Y_{F,u}} \bigg|_{st} = \frac{\nu'_{O_2} W_{O_2}}{\nu'_F W_F} = \nu \]
The Mixture Fraction

• The mixture fraction is an extremely useful variable in combustion in particular for diffusion flames

• Here we present it first for a homogeneous system

• In a two-feed system a fuel stream (subscript 1) with mass flux \( m_1 \) is mixed with an oxidizer stream (subscript 2) with mass flux \( m_2 \)

• The mixture fraction represents the mass fraction of the fuel stream in the mixture:

\[
Z = \frac{m_1}{m_1 + m_2}
\]

• Both fuel and oxidizer streams may contain inerts such as nitrogen
• The mass fraction $Y_{F,u}$ of the fuel in the mixture is proportional to the mass fraction in the original fuel stream, so

\[ Y_{F,u} = Y_{F,1} \cdot Z \]

where $Y_{F,1}$ denotes the mass fraction of fuel in the fuel stream.

• Similarly, since $1-Z$ represents the mass fraction of the oxidizer stream in the mixture, one obtains for the mass fraction of oxygen in the mixture

\[ Y_{O_2,u} = Y_{O_2,2} (1 - Z) \]

where $Y_{O_2,2}$ represents the mass fraction of oxygen in the oxidizer stream ($Y_{O_2,2} = 0.232$ for air).
• Introducing

\[ Y_{F,u} = Y_{F,1}Z \]

and

\[ Y_{O_2,u} = Y_{O_2,2}(1 - Z) \]

into

\[ \nu Y_F - Y_{O_2} = \nu Y_{F,u} - Y_{O_2,u} \]

one obtains the mixture fraction as a variable that couples the mass fractions of the fuel and the oxygen

\[ Z = \frac{\nu Y_F - Y_{O_2} + Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}} = -\frac{Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}} + Z_{st} \]

• For a stoichiometric mixture one obtains with \( \nu Y_F = Y_{O_2} \)

the stoichiometric mixture fraction

\[ Z_{st} = \frac{Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}} \]
• Profiles of $Y_F$ and $Y_{O_2}$ in the unburnt gas
• If $Z < Z_{st}$ fuel is deficient and the mixture is called fuel lean.

• Then, combustion terminates when all the fuel is consumed: $Y_{F,b} = 0$ (burnt gas, subscript $b$).

• The remaining oxygen mass fraction in the burnt gas is calculated from

\[
Z = \frac{\nu Y_F - Y_{O_2} + Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}}
\]

as

\[
Y_{O_2,b} = Y_{O_2,2}(1 - \frac{Z}{Z_{st}}), \quad Z \leq Z_{st}
\]

where

\[
Z_{st} = \frac{Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}}
\]
• Similarly, if $Z > Z_{st}$ oxygen is deficient and the mixture is called \textit{fuel rich}.

• Combustion then terminates when all the oxygen is consumed: \quad $Y_{O_2,b} = 0$

• Leading to

\[
Y_{F,b} = Y_{F,1} \frac{Z - Z_{st}}{1 - Z_{st}}, \quad Z \geq Z_{st}
\]

• For the hydrocarbon fuel considered above the element mass fractions in the unburnt mixture are

\[
Z_C = m \frac{W_C}{W_F} Y_{F,u}, \quad Z_H = n \frac{W_H}{W_F} Y_{F,u}, \quad Z_O = Y_{O_2,u}
\]

or

\[
\frac{Z_C}{mW_C} = \frac{Z_H}{nW_H} = \frac{Y_{F,u}}{\nu'_FW_F}
\]
• For a stoichiometric mixture where

$$\frac{Y_{O_2,u}}{\nu'_{O_2}W_{O_2}} = \frac{Y_{F,u}}{\nu'_{F}W_{F}}$$

it follows that the combination

$$\beta = \frac{Z_C}{mW_C} + \frac{Z_H}{nW_H} - 2\frac{Z_O}{\nu'_{O_2}W_{O_2}}$$

vanishes
• Normalizing this such that \( Z = 1 \) in the fuel stream and \( Z = 0 \) in the oxidizer stream, one obtains Bilger's definition

\[
Z = \frac{\beta - \beta_2}{\beta_1 - \beta_2}
\]

or

\[
Z = \frac{Z_C/(mW_C) + Z_H/(nW_H) + 2(Y_{O_2,u} - Z_O)/(\nu'_{O_2} W_{O_2})}{Z_{C,1}/(nW_C) + Z_{H,1}/(mW_H) + 2Y_{O_2,u}/(\nu'_{O_2} W_{O_2})}
\]

• Because elements are conserved during combustion, the element mass fractions calculated from

\[
Z_j = \frac{m_j}{m} = \sum_{i=1}^{k} \frac{a_{ij}W_j}{W_i}Y_i = \frac{W_j}{W} \sum_{i=1}^{k} a_{ij}X_i, \quad j = 1, 2, \ldots, k_e,
\]

do not change
- For the burnt gas they are for the hydrocarbon fuel considered above

\[
Z_C = m \frac{W_C}{W_F} Y_{F,b} + \frac{W_C}{W_{CO_2}} Y_{CO_2,b}
\]

\[
Z_H = n \frac{W_H}{W_F} Y_{F,b} + 2 \frac{W_H}{W_{H_2O}} Y_{H_2O,b}
\]

\[
Z_O = 2 \frac{W_O}{W_{O_2}} Y_{O_2,b} + 2 \frac{W_O}{W_{CO_2}} Y_{CO_2,b} + \frac{W_O}{W_{H_2O}} Y_{H_2O,b}
\]
• This leads with \( Y_{F,u} = Y_{F,1} Z \) and \( Y_{F,b} = 0 \) for \( Z \leq Z_{st} \)

\[
Z = \frac{\nu Y_F - Y_{O_2} + Y_{O_2,2}}{\nu Y_{F,1} + Y_{O_2,2}} \quad \text{for} \quad Z \geq Z_{st}
\]

This leads to piecewise linear relations of the product mass fractions in terms of \( Z \):

\[
Z \leq Z_{st} : \quad Y_{CO_2,b} = Y_{CO_2,sta} \frac{Z}{Z_{st}} \quad Y_{H_2O,b} = Y_{H_2O,sta} \frac{Z}{Z_{st}}
\]

\[
Z \geq Z_{st} : \quad Y_{CO_2,b} = Y_{CO_2,sta} \frac{1 - Z}{1 - Z_{st}} \quad Y_{H_2O,b} = Y_{H_2O,sta} \frac{1 - Z}{1 - Z_{st}}
\]

where

\[
Y_{CO_2,sta} = Y_{F,1} Z_{st} \frac{mW_{CO_2}}{W_F}
\]
• Profiles in the burning mixture
• The fuel-air equivalence ratio is the ratio of fuel-air ratio in the unburnt to that of a stoichiometric mixture

\[
\phi = \frac{Y_{F,u}/Y_{O2,u}}{(Y_{F,u}/Y_{O2,u})_{st}} = \frac{\nu Y_{F,u}}{Y_{O2,u}}
\]

• Introducing \( Y_{F,u} = Y_{F,1} Z \) and \( Y_{O2,u} = Y_{O2,2} (1 - Z) \)

\[
\nu Y_F - Y_{O2} = \nu Y_{F,u} - Y_{O2,u}
\]

into

\[
\frac{\nu Y_{F,1}}{Y_{O2,2}} = \frac{1 - Z_{st}}{Z_{st}}
\]

leads with

\[
\phi = \frac{Z}{1 - Z} \left(1 - Z_{st}\right)
\]

to a unique relation between the equivalence ratio and the mixture fraction.
• This relation is also valid for multicomponent fuels (*Exercise*)

• It illustrates that the mixture fraction is simply another expression for the local equivalence ratio

• *Exercise:*

  • *The element mass fractions* $Z_{H,F}, Z_{C,F}$ *of a mixture of hydrocarbons and its mean molecular weight* $W$ *are assumed to be known.*

  • *Determine its stoichiometric mixture fraction in air.*

  • *A hint:* $Z_{H,F} = n W_H / W$, $Z_{C,F} = m W_C / W$
